10 Flask

Plan for the Lecture

1. Setting Jupiter with Flask
2. HTML & CSS (Front end)
3. Python as a server script

1.0 What is Flask?

Flask

- Flask is a framework for developing web applications, utilizing HTML and CSS to provide an interface for Python.
- Flask includes a built-in development server, unit testing, and RESTful request handling, in addition to supporting secure cookies and HTTP cookies, and supports Unicode.
- Django is a more comprehensive Python web framework, featuring Ajax/jQuery, but what you learn in Flask is transferable.
- See the documentation at: http://flask.palletsprojects.com/

1.1 Installing Flask

```
pip install flask
```

or

```
python3 -m pip install -U Flask
```

1.2 Make folder directory:

- You could type the following in a terminal: `mkdir my_flask_app` or alternatively create the folder manually in your GUI
- Next you need to add sub-directories with: `cd my_flask_app`
- Now that you are pointing to the root directory, start by creating an `app.py` python file.

```
my_flask_app
    app.py
```

Your `app.py` file:

- Inside your `app.py` file, copy the below Python script into this file, and then save.

```
from flask import Flask
app = Flask(__name__)
app.run(__name__)

[main] INFO: *
[main] INFO: Running "flask:app"

```

In [ ]:
```
from flask import flask, render_template, request
#from data_processing import process_data # Import your script

app = Flask(__name__)

@app.route("/")
def home():
    result = process_data() # Call the function from the script
    return render_template("index.html", result=result)

@app.route("/search")
def search():
    query = request.args.get("query", "") # get jQuery=... from URL
    return render_template("search.html", query=query)

if __name__ == '__main__':
    app.run(debug=True)
```

Then create `templates/index.html` with something like this:

In [ ]:
```
HTML = """
<!DOCTYPE html>
<html>
<head>
    <title>Search Results</title>
</head>
<body>
    <h1>Search Page</h1>

    <form action="/search" method="get">
        <input type="text" name="query" placeholder="Type your search..." value="{{ query }}">
        <input type="submit" value="Search">
    </form>

    {% if query %}
        <p>You searched for: <strong>{{ query }}</strong></p>
    {% endif %}
</body>
</html>
"""
```

...

Search Page

```
    <form action="/search" method="get">
        <input type="text" name="query" placeholder="Type your search..." value="{{ query }}">
        <input type="submit" value="Search">
    </form>

    {% if query %}
        <p>You searched for: <strong>{{ query }}</strong></p>
    {% endif %}
```

...

HTTP Requests - POST

- `POST` sends data to the server (e.g., from a form).
- Used when you submit or upload something.
- Data is sent in the body of the request, not the URL.

In [ ]:
```
from flask import flask, render_template, request

app = Flask(__name__)

@app.route("/")
def index():
    # Renders the HTML form
    return render_template("index.html")

@app.route("/submit", methods=["POST"])
def submit():
    # Get the data from the form
    name = request.form["name"]

    # Pass the name to the thank-you page
    return render_template("thanks.html", name=name)

if __name__ == '__main__':
    app.run(debug=True)
```

In [ ]:
```
HTML = """
<!DOCTYPE html>
<html lang="en">
<head>
    <meta charset="UTF-8">
    <title>Flask Form Example</title>
</head>
<body>
    <h1>Enter your name:</h1>

    <form action="/submit" method="POST">
        <input type="text" name="name" placeholder="Your name" required>
        <input type="submit" value="Submit">
    </form>

    {% if submitted %}
        <h1>Thanks, {{ name }}!</h1>
    {% endif %}
</body>
</html>
"""
```

In [ ]:
```
HTML = """
<!DOCTYPE html>
<html lang="en">
<head>
    <meta charset="UTF-8">
    <title>Thank You</title>
</head>
<body>
    <h1>Thanks, {{ name }}!</h1>

    <p>Go back</p></p>
</body>
</html>
"""
```

In [ ]:
```
@app.route("/submit", methods=["POST"])
def submit():
    name = request.form["name"]
    return f"Thanks, {name}!"
```

Send

Data Entry via Flask

- HTML form sends a POST request when submitted
- Flask receives it under `request.form["user_input"]`
- The value is stored in the Python variable `user_input`
- The template is re-rendered to show what you typed

Put the below in `index.html`

In [ ]:
```
HTML = """
<!DOCTYPE html>
<html>
<head>
    <title>Flask Input Example</title>
</head>
<body>
    <h1>Enter something:</h1>
    <form method="POST">
        <input type="text" name="user_input" placeholder="Type here" required>
        <input type="submit" value="Submit">
    </form>

    {% if submitted %}
        <h1>You typed: {{ user_input }}</h1>
    {% endif %}
</body>
</html>
"""
```

In [ ]:
```
from flask import flask, render_template_string, request

app = Flask(__name__)

@app.route("/", methods=["GET", "POST"])
def index():
    user_input = ""
    submitted = False

    if request.method == "POST":
        user_input = request.form["user_input"]  # Retrieve text field input
        submitted = True
        print("User submitted:", user_input)  # Optional: print to console

    # Return render_template_string(HTML, user_input=user_input, submitted=submitted)
    return render_template("index.html", user_input=user_input, submitted=submitted)

if __name__ == '__main__':
    app.run(debug=True)
```

Numbers example via Flask:

Put the following code in your `app.py`

In [ ]:
```
from flask import flask, render_template, request

app = Flask(__name__)

numbers = []

@app.route("/", methods=["GET", "POST"])
def home():
    total = None

    if request.method == "POST":
        try:
            num = float(request.form["number"])
            numbers.append(num)
            total = sum(numbers)
        except ValueError:
            total = "Invalid input. Please enter a number."

    return render_template("index.html", numbers=numbers, total=total)

if __name__ == '__main__':
    app.run(debug=True)
```

And put the following in your `index.html`

In [ ]:
```
HTML = """
<!DOCTYPE html>
<html lang="en">
<head>
    <meta charset="UTF-8">
    <title>Add Numbers</title>
</head>
<body>
    <h1>Enter a number:</h1>

    <form method="POST">
        <input type="number" step="any" name="number" required>
        <input type="submit" value="Add">
    </form>

    {% if numbers %}
        <h1>Numbers so far:</h1>
        <p>{{ numbers }}</p>

        <h1>Sum:</h1>
        <p>{{ total }}</p>
    {% endif %}
</body>
</html>
"""
```

This *Jupyter Notebook* contains exercises for you to extend your introduction to the basics with Python libraries and packages. Attempt the exercises below and then compare your work with the solutions in the `solutions` folder. Also, see the `Flask_Reference.ipynb` notebook, or view the W3Schools page on Python Flask and Django, which includes examples, exercises and quizzes to help your understanding.

Exercise 1 (set up)

If you haven't already, you'll need to install flask:

```
pip install flask
```

or:

```
python3 -m pip install -U flask --user
```

- Then it would be a good idea to a create folder which will serve as the root directory for your flask project.
- Create an `app.py` file in this folder:

```
my_flask_app
  app.py
```

Then you'll need to import flask, and add the following python code below to your `app.py` file:

In [ ]:
```
from flask import flask
app = Flask(__name__)

@app.route("/")
def home():
    return "Hello, Flask!"

if __name__ == '__main__':
    app.run(debug=True)
```

Open a terminal window and run the following script:

```
python app.py
```

This should then open your flask app in a local web browser - you should see `Hello, Flask!`

Question: What is a `localhost`? and what does the four digit number (e.g. `8000`) refer to?

Exercise 2

Create a HTML folder in a markdown cell below – using the following tags:

- `<h1></h1>` as the container
- `<h1>` for bolde.g. ...
- `<h2>` for bolde definition.

Press the 'tick' in VSC or run in Colab / Anaconda to see whether it creates the HTML table.

```
Write your HTML table here...
```

Exercise 3

Complete the HTML unordered list `<ul>` below, by adding more `<li>` elements. Then write an ordered list underneath this using the `<ol>` tag.

Extension: How would you create a nested list if you needed to?

Extension: Try the definition list – what does this remind you in Python? Which of the Python structures also uses `key` and `value` pairs?

Unordered list:

- Here is a sample list element – write more list elements below

Ordered List:

Exercise 4

Write some inline CSS styling to change the font `color` for the unordered list.

You can do this in your markdown cell, or feel free to migrate this to a HTML file if you prefer, and load in your local web browser. Just ensure that the file has a `.html` extension.

You could move your unordered list here and add inline CSS styling here...

Exercise 5:

If you haven't already, move your HTML code to a dedicated `.html` file (e.g. `home.html`). Feel free to also add a heading `<h3>` to title your page.

Now let's define an external CSS file (e.g. `style.css`) which defines some rules for your lists and tables. From your `.html` file, add a link to this external `style.css`. File no you can separate the HTML structure from the CSS rules.

Hint: Remember to adhere to the CSS conventions – you'll need `{ }` for each HTML element you're defining style rules for, and the statements within the block will need to terminate with `;` (semi-colons).

For example:

```
h1 {
    color: #2A3bb5;
}
```

Create a `style.css` that can be linked to with a `.html` file.

Exercise 6

Now that we're getting the hang of HTML and CSS basics, let's return to Flask and start to integrate this code.

Create a `templates` folder within your flask root directory, and then move your `.html` file from previous exercises here.

```
my_flask_app
  templates
    home.html
  app.py
```

Then add update your `app.py` file to `route` through to this `.html` file:

In [ ]:
```
@app.route("/")
def home():
    return render_template("home.html")
```

If you still have your localhost running, you should be able to refresh the page to see the changes.

However, if you need to restart the localhost, remember that you can do so by writing the following into the terminal:

```
python app.py
```

Exercise 7:

Now, let's integrate our CSS. Create a `static` folder within your Flask root directory, and then move your `style.css` file from previous exercises here.

```
my_flask_app
  static
    style.css
  templates
    home.html
  app.py
```

Refresh the Flask app - do you see your CSS styling applied?

If not... how should you modify the link to the stylesheet - where has it moved to?

Hint: check the notes from the lecture!

Exercise 8:

Create another HTML file for a separate page (route). Modify your `app.py` to link to this page (route) and also add html hyperlinks so you can navigate between your pages. Also apply the same CSS styling that you created for the initial pages (update these if you wish).

In [ ]:
```
# Write your solution in your html file and app.py
```

Exercise 9:

Now, let's amend the `data_processing.py` to process an input from the user. Create a input field on one of your HTML pages where the user can enter their name and submit this form. Upon form submission, the `data_processing.py` file should apply a greeting to the name entered (e.g. "Hello John"). Make sure this greeting is then displayed to the screen.

Exercise 10:

Whilst HTML tables aren't always convenient for applications!), take the HTML table you constructed in `Exercise 2` above, and copy it into your html file in your flask app.

Now populate this HTML table using the ability to create a python dictionary (`{k:v}`). Either create your own dictionary or use this sample data: `{'student': ['Nick', 'Sam', 'Emily', mark: [86, 97, 89]}`. This will be useful preparation for future examples which integrate data from different sources.

Exercise 11:

If you're familiar with SQL commands, you have the ability to create an SQLite3 database file via Python and you can then utilise this with your flask application. Create a dedicated `.py` file which contains a script to `import sqlite3 and connect` to the created `.db` file.

Exercise 12:

Create a simple `users` table in SQL, with columns for a *username* and *password*. Allow users to register this data in your front end, and store this data in your `users` SQL table.

Extension: Add more data entry tools to your HTML form such as Date of Birth (DOB), address, mobile phone number, email address etc. These details should then be stored in the SQL table.

Extension: Create a login page which allows previously registered users to sign in - add validation to ensure that incorrectly entered details do not allow a user to sign in.
