

'Reliable' Programming

Examples from Sommerville's 2018 book: "Engineering Software Products,
An Introduction to Modern Software Engineering"

Software Quality: Reliability

- Reliability is similar to trust
- Users want to know that software will perform consistently each time they use it.
 - If WhatsApp only sent 50% of our texts, that wouldn't be very useful...
 - Likewise, we want Amazon to store keep our data safe...
 - We certainly want aeroplanes to take off and land safely 100% of the time!

Three ways to improve reliability

- **Fault avoidance** - You should program in such a way that you avoid introducing faults into your program.
- **Input validation** - You should define the expected format for user inputs and validate that all inputs conform to that format.
- **Failure management** - You should implement your software so that program failures have minimal impact on product users.

Programmers make mistakes because they don't properly understand the problem or the application domain.

Problem

Programmers make mistakes because they use unsuitable technology or they don't properly understand the technologies used.

Technology

Programming language, libraries, database, IDE, etc.

Program

Programmers make mistakes because they make simple slips or they do not completely understand how multiple program components work together and change the program's state.

Single Responsibility

- Classes should model **one** entity:
 - Student
 - Player
 - NOT Student_Player_and_Course
- Attributes of a class obviously store **one** value at a time
- Methods to perform **one** action:
 - print()
 - remove()
 - insert()
 - NOT print_and_remove_and_insert_new()
- Single responsibility encourages cohesion and reuse within programs

Types of Complexity: Structural

- **Structural complexity**

- Functions should do one thing and one thing only
- Functions should never have side-effects
- Every class should have a single responsibility
- Minimize the depth of inheritance hierarchies
- Avoid multiple inheritance
- Avoid threads (parallelism) unless absolutely necessary

Types of Complexity: Conditional

- **Conditional complexity**
 - Avoid deeply nested conditional statements
 - Avoid complex conditional expressions
- Deeply nested conditional (if) statements are used when you need to identify which of a possible set of choices is to be made.
- Consider the example code on the next slide

```
# Deeply nested if else statements
YOUNG_DRIVER_AGE_LIMIT = 25
OLDER_DRIVER_AGE = 70
ELDERLY_DRIVER_AGE = 80
YOUNG_DRIVER_PREMIUM_MULTIPLIER = 2
OLDER_DRIVER_PREMIUM_MULTIPLIER = 1.5
ELDERLY_DRIVER_PREMIUM_MULTIPLIER = 2
YOUNG_DRIVER_EXPERIENCE_MULTIPLIER = 2
NO_MULTIPLIER = 1
YOUNG_DRIVER_EXPERIENCE = 2
OLDER_DRIVER_EXPERIENCE = 5
def age_check (age, experience):
    # Premium multiplier depending on age and experience
    multiplier = NO_MULTIPLIER
    if age <= YOUNG_DRIVER_AGE_LIMIT:
        if experience <= YOUNG_DRIVER_EXPERIENCE:
            multiplier = (YOUNG_DRIVER_PREMIUM_MULTIPLIER *
                          YOUNG_DRIVER_EXPERIENCE_MULTIPLIER)
        else:
            multiplier = YOUNG_DRIVER_PREMIUM_MULTIPLIER
    else:
        if age > OLDER_DRIVER_AGE and age <= ELDERLY_DRIVER_AGE:
            if experience <= OLDER_DRIVER_EXPERIENCE:
                multiplier = OLDER_DRIVER_PREMIUM_MULTIPLIER
            else:
                multiplier = NO_MULTIPLIER
        else:
            if age > ELDERLY_DRIVER_AGE:
                multiplier = ELDERLY_DRIVER_PREMIUM_MULTIPLIER
    return multiplier
```

Example of Condition Complexity

- Deeply nested conditional (if) statements are used when you need to identify which of a possible set of choices is to be made.
- For example, the function 'age_check' is a short Python function that is used to calculate an age multiplier for insurance premiums.
- The insurance company's data suggests that the age and experience of drivers affects the chances of them having an accident, so premiums are adjusted to take this into account.
- It is good practice to name constants rather than using absolute numbers, so the program names all constants that are used.

```

# Deeply nested if else statements
YOUNG_DRIVER_AGE_LIMIT = 25
OLDER_DRIVER_AGE = 70
ELDERLY_DRIVER_AGE = 80
YOUNG_DRIVER_PREMIUM_MULTIPLIER = 2
OLDER_DRIVER_PREMIUM_MULTIPLIER = 1.5
ELDERLY_DRIVER_PREMIUM_MULTIPLIER = 2
YOUNG_DRIVER_EXPERIENCE_MULTIPLIER = 2
NO_MULTIPLIER = 1
YOUNG_DRIVER_EXPERIENCE = 2
OLDER_DRIVER_EXPERIENCE = 5
def age_check (age, experience):
    # Premium multiplier depending on age and experience
    multiplier = NO_MULTIPLIER
    if age <= YOUNG_DRIVER_AGE_LIMIT:
        if experience <= YOUNG_DRIVER_EXPERIENCE:
            multiplier = (YOUNG_DRIVER_PREMIUM_MULTIPLIER *
                          YOUNG_DRIVER_EXPERIENCE_MULTIPLIER)
        else:
            multiplier = YOUNG_DRIVER_PREMIUM_MULTIPLIER
    else:

Structural complexity: avoid deep inheritance

- Inheritance appears to be an effective and efficient way of reusing code and of making changes that affect all subclasses.
- However, inheritance increases the structural complexity of code as it increases the coupling of subclasses. The diagram shows part of a 4-level inheritance hierarchy that could be defined for staff in a hospital.

Structural complexity: avoid deep inheritance

- The problem with deep inheritance is that if you want to make changes to a class, you have to look at all of its superclasses to see where it is best to make the change.
- You also have to look at all of the related subclasses to check that the change does not have unwanted consequences. It's easy to make mistakes when you are doing this analysis and introduce faults into your program.

Measuring Quality: Code Metrics in VS22

| Code Metrics Results | | | | | | |
|---------------------------|--|---------------------|---------------------|----------------|---------------------|---------------------|
| Filter: None Min: Max: | | | | | | |

Refactoring

Refactoring is a systematic process of improving code without creating new functionality that can transform a mess into clean code and simple design.

Start from the very beginning

Dirty Code

Dirty code is result of inexperience multiplied by tight deadlines, mismanagement, and nasty shortcuts taken during the development process.

[Learn more](#)

Clean Code

Clean code is code that is easy to read, understand and maintain. Clean code makes software development predictable and increases the quality of a re

[Learn more](#)

Refactoring Process

Performing refactoring step-by-step and running tests after each change are key elements of refactoring that make it predictable and safe.

[Learn more](#)

Code Smells

Code smells are indicators of problems that addressed during refactoring. Code smells are easy to spot and fix, but they may be just symptoms of a deeper problem with code.

Refactoring Techniques

Refactoring techniques describe actual refactoring steps. Most refactoring techniques have their pros and cons. Therefore, each refactoring should be properly motivated and applied with caution.

Code 'smells'

- **'Code smells' are indicators in the code that there might be a deeper problem.**
- Martin Fowler, a refactoring pioneer, suggests that the starting point for refactoring should be to identify code smells.
- For example, very large classes may indicate that the class is trying to do too much. This probably means that its structural complexity is high.

Martin Fowler

Examples of Code 'smells'

Large classes

- Large classes may mean that the single responsibility principle is being violated.
- Break down large classes into easier-to-understand, smaller classes.

Long methods/functions

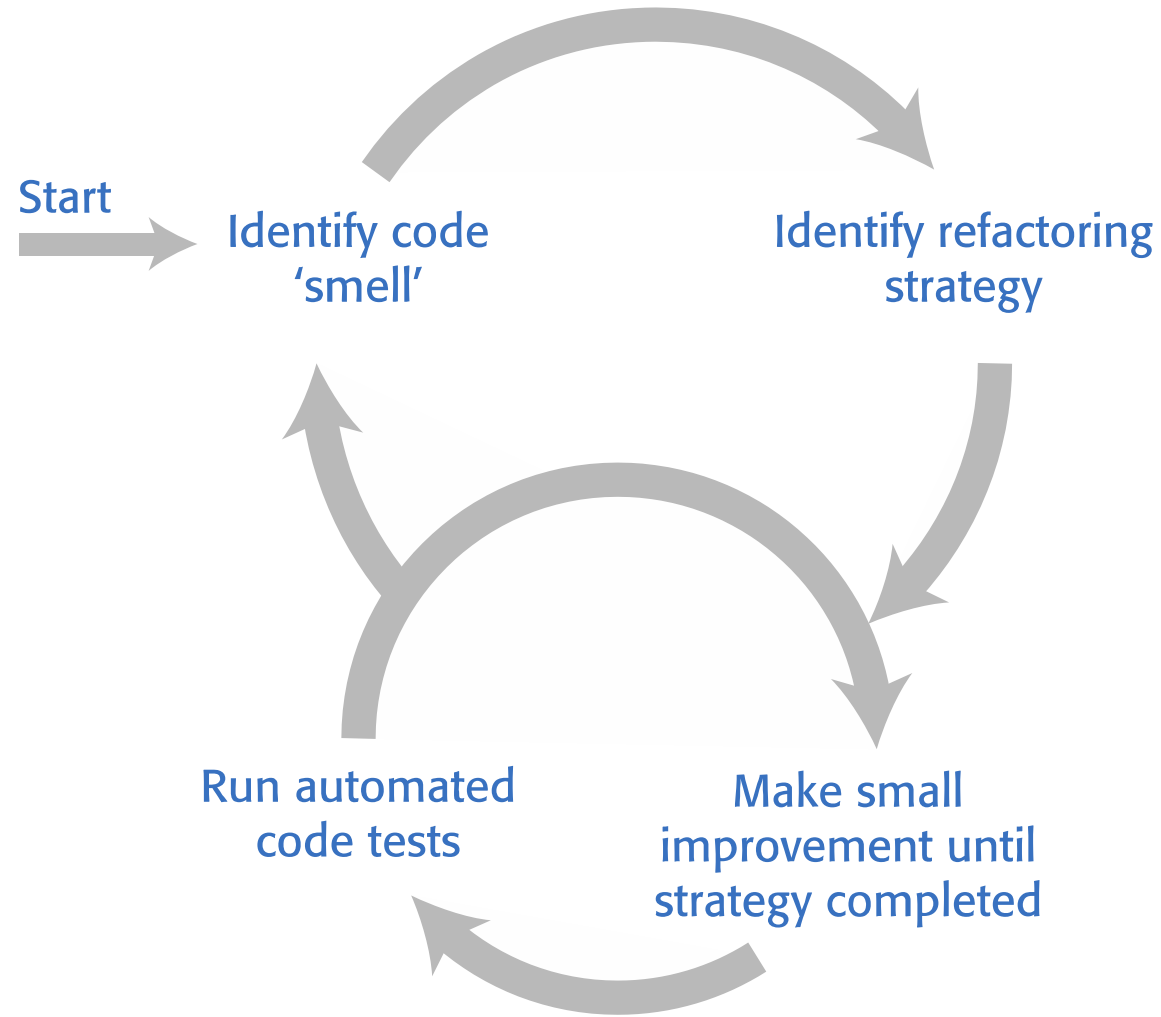

- Long methods or functions may indicate that the function is doing more than one thing.
- Split into smaller, more specific functions or methods.

Duplicated code

- Duplicated code may mean that when changes are needed, these have to be made everywhere the code is duplicated.
- Rewrite to create a single instance of the duplicated code that is used as required

Meaningless names

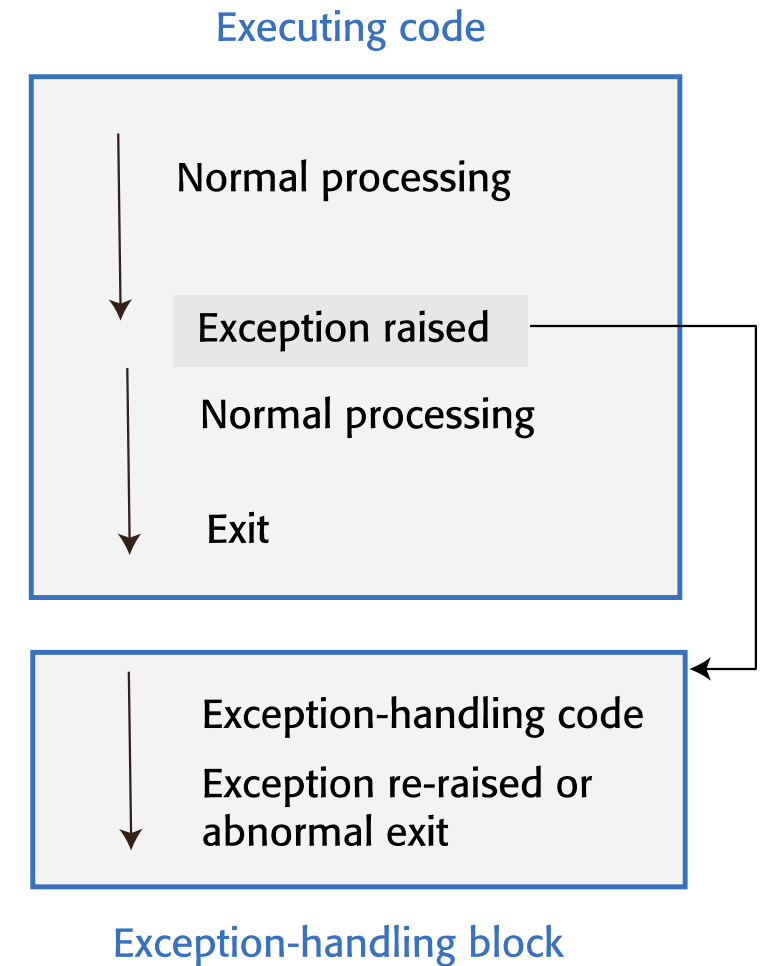

- Meaningless names are a sign of programmer haste. They make the code harder to understand.
- Replace with meaningful names and check for other shortcuts that the programmer may have taken.

- Refactoring means changing a program to reduce its complexity without changing the external behaviour of that program.

Exception Handling

- Exceptions are events that disrupt the normal flow of processing in a program.
- In Python, you use **try-except** keywords to indicate exception handling code; in Java, the equivalent keywords are **try-catch**.

Exception Handling

- Code functions to raise (throw) exceptions
- Then these objects can be 'caught' elsewhere

```
1 def withdraw(amount, balance):
2     if amount > balance:
3         raise ValueError("Insufficient funds.")
4     balance -= amount
5     return balance
```

```
1 withdraw(100, 50)
```

```
-----
ValueError                                Traceback (most recent call last)
Cell In [60], line 1
----> 1 withdraw(100, 50)

Cell In [59], line 3
      1 def withdraw(amount, balance):
      2     if amount > balance:
----> 3         raise ValueError("Insufficient funds.")
      4     balance -= amount
      5     return balance

ValueError: Insufficient funds.
```

Assertions

- Assertions can be used to check parameters of methods, or values of variables.

```
1 x = 5
2 assert x > 10, "x has to be greater than 10"
```

⊗ 0.2s

AssertionError Traceback (most recent call last)

Cell In [1], [line 2](#)

[1](#) x = 5

----> [2](#) assert x > 10, "x has to be greater than 10"

AssertionError: x has to be greater than 10

Debugging

```
mirror_mod = modifier_ob.  
#set mirror object to mirror_  
mirror_mod.mirror_object =  
operation == "MIRROR_X":  
mirror_mod.use_x = True  
mirror_mod.use_y = False  
mirror_mod.use_z = False  
operation == "MIRROR_Y":  
mirror_mod.use_x = False  
mirror_mod.use_y = True  
mirror_mod.use_z = False  
operation == "MIRROR_Z":  
mirror_mod.use_x = False  
mirror_mod.use_y = False  
mirror_mod.use_z = True  
  
#selection at the end -add  
mirror_ob.select= 1  
modifier_ob.select=1  
context.scene.objects.active  
("Selected" + str(modifier_ob.  
mirror_ob.select = 0  
= bpy.context.selected_object  
data.objects[one.name].select  
  
print("please select exactly  
  
--- OPERATOR CLASSES ---  
  
types.Operator):  
on X mirror to the selected  
object.mirror_mirror_x"  
mirror X"  
  
context):  
context.active_object is not
```

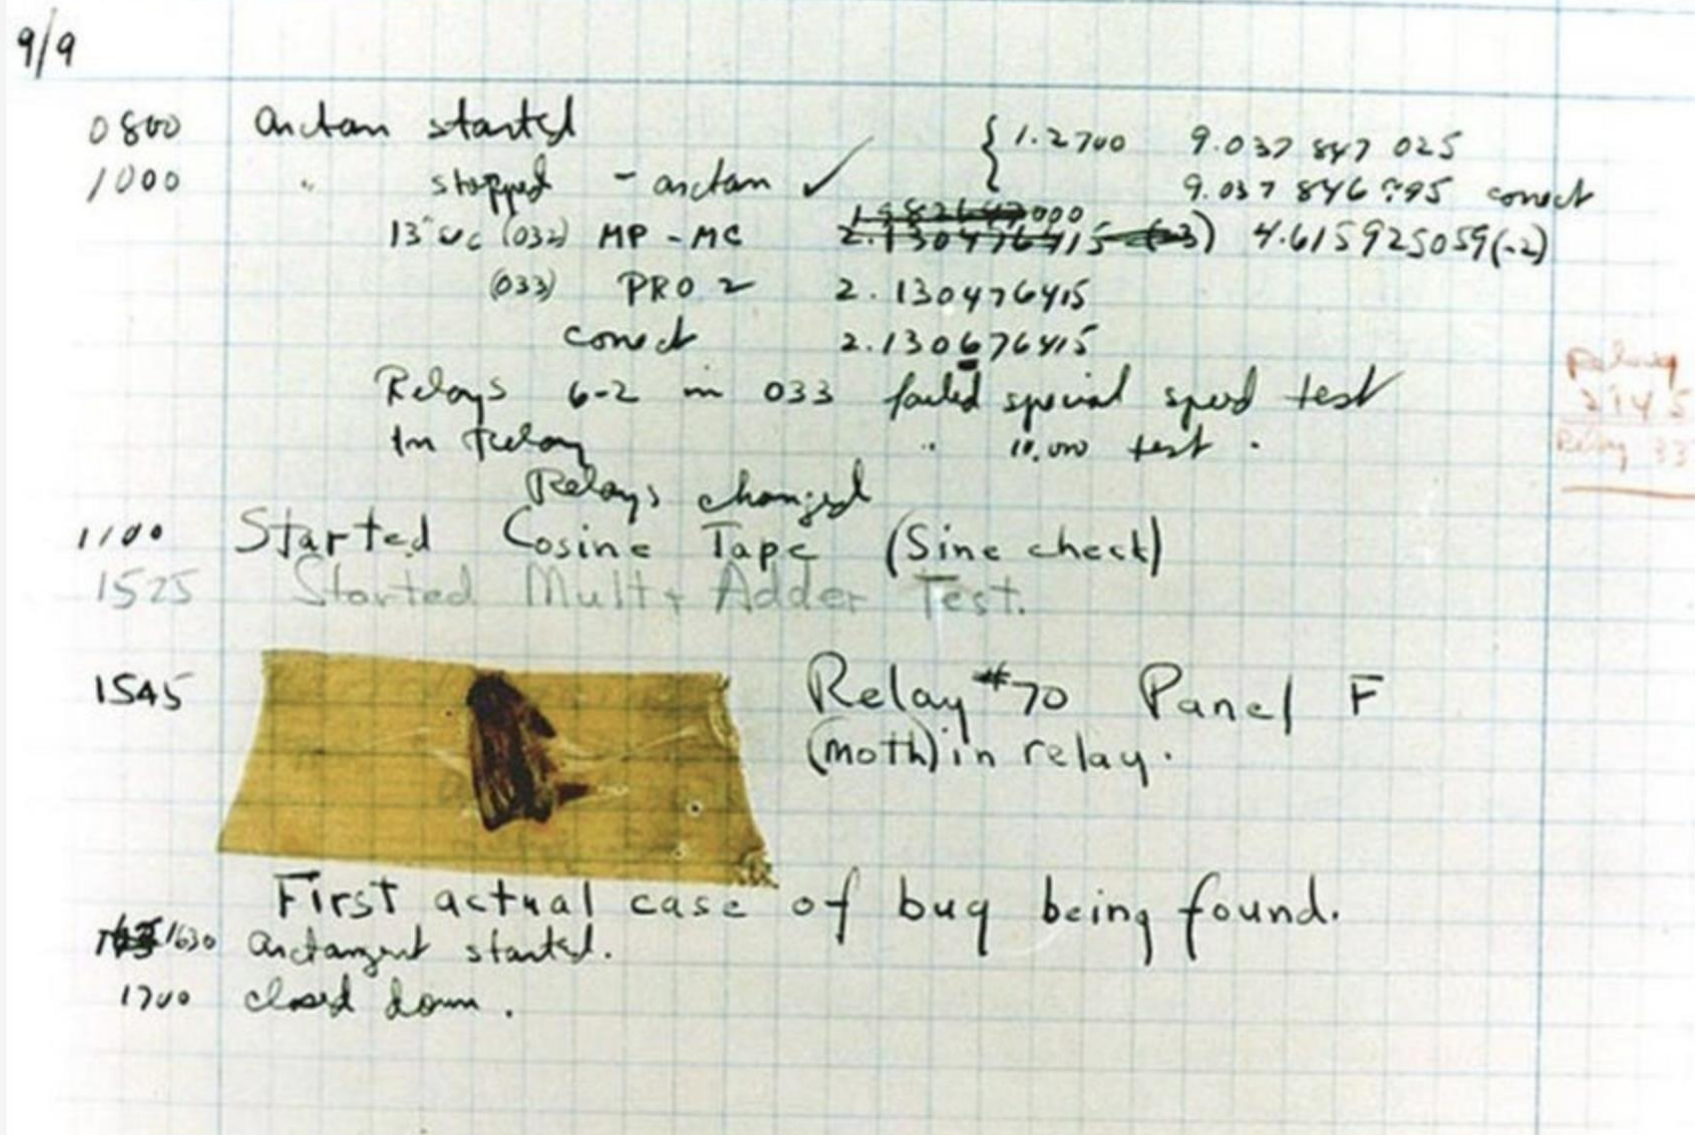

First bug!

PHOTOGRAPH

Computer Bug

"First actual case of bug being found," according to the brainiacs at Harvard, 1945. The engineers who found the moth were the first to literally "debug" a machine.

Run 'with' debugging

- Click just left of a line number in an IDE to add a breakpoint.
- Break points pause execution at specific lines so you can inspect variables and program flow.
- Step by step execution
- Debug Console (or log in Unity)
- Call Stack
- Exception Tracking

The screenshot shows a code editor with a dark blue background. A red dot on the left margin indicates a breakpoint set at line 6. A tooltip above the breakpoint says "Click to add a breakpoint". The code is in Python and shows a try-except block. The exception being handled is a ZeroDivisionError, and the message printed is "You cannot divide by zero!". The output of the program is also shown at the bottom of the editor.

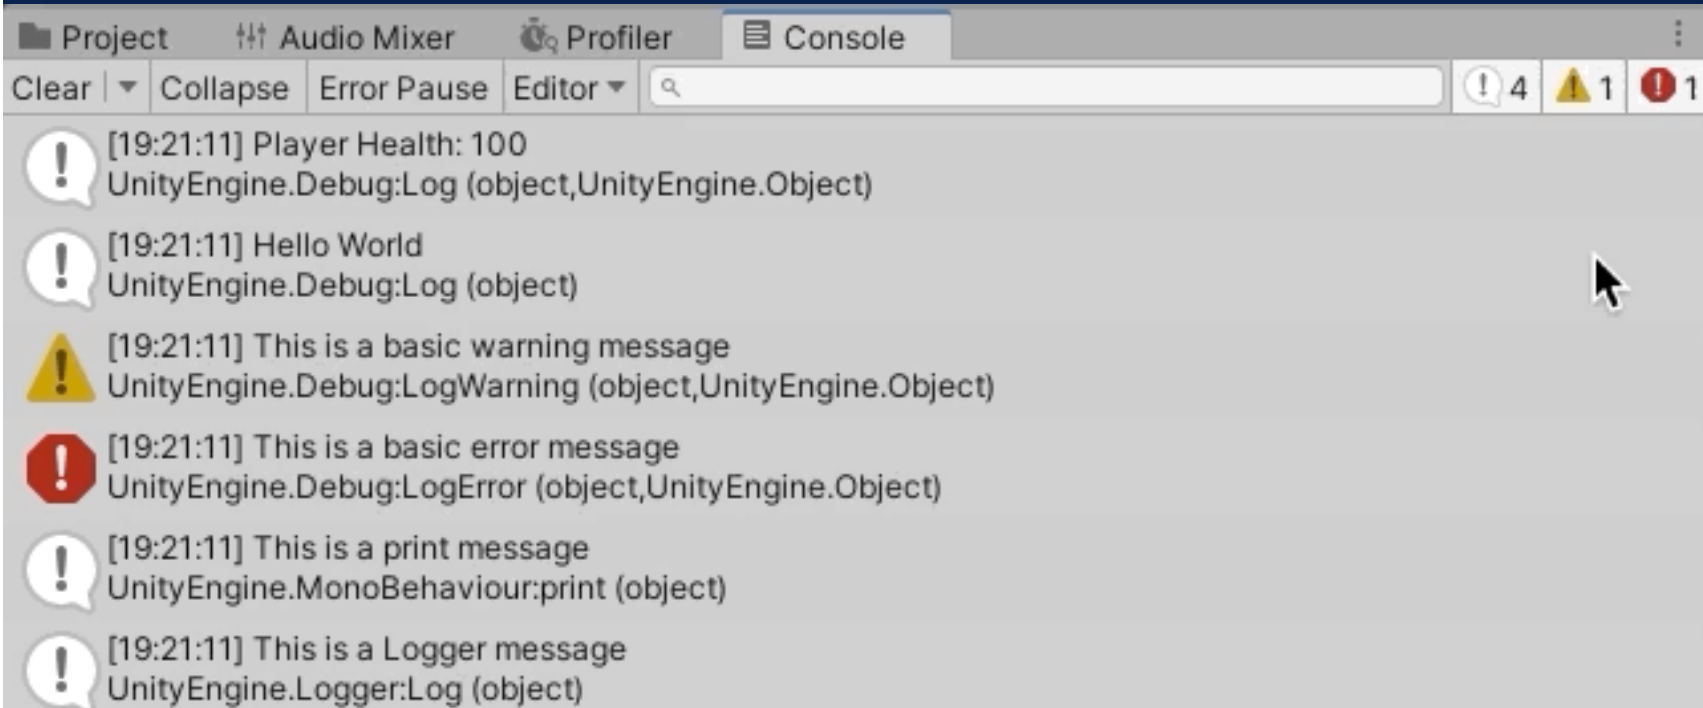

```
1 try:  
2     # Code to handle the exception  
3     print("You cannot divide by zero!")  
4 except ZeroDivisionError:  
5     print("You cannot divide by zero!")  
6  
7
```

You cannot divide by zero!

Unity Debug Console

0 references

```
void OnCollisionEnter2D(Collision2D collision)
{
    //collisionText.text = "Collided with: " + collision.gameObject.name;
    // Print a message to the Console when a 2D collision occurs
    Debug.Log("Collided with: " + collision.gameObject.name);
}
```

The screenshot shows the Unity Debug Console interface. At the top, there are tabs for 'Project', 'Audio Mixer', 'Profiler', and 'Console'. Below the tabs, there is a search bar and a row of icons: a speech bubble with an exclamation mark (4), a yellow triangle with an exclamation mark (1), and a red circle with an exclamation mark (1). The main area displays a list of log messages, each preceded by an icon indicating its severity:

- [19:21:11] Player Health: 100
UnityEngine.Debug:Log (object,UnityEngine.Object)
- [19:21:11] Hello World
UnityEngine.Debug:Log (object)
- [19:21:11] This is a basic warning message
UnityEngine.Debug:LogWarning (object,UnityEngine.Object)
- [19:21:11] This is a basic error message
UnityEngine.Debug:LogError (object,UnityEngine.Object)
- [19:21:11] This is a print message
UnityEngine.MonoBehaviour:print (object)
- [19:21:11] This is a Logger message
UnityEngine.Logger:Log (object)

Visual Studio Code Debug

Start debugging

Pause, step over, step in/out, restart, stop
